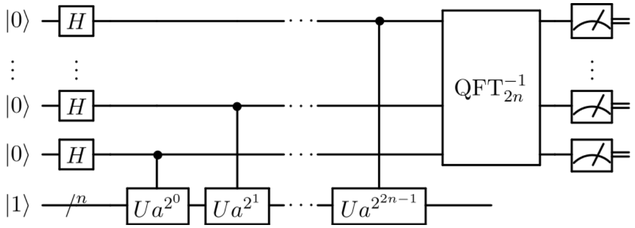
# 1994 - Shor's algorithm

Peter Shor, professor of Applied mathematics at MIT

"Shor's algorithm is a quantum algorithm for factoring the prime factors of an integer" (source: Wikipedia) (semiprime)

Fourier transform on a quantum processor…



## Practical implementation

Factoring a 2,048 bit integer would require approx. 4,000 perfect qubits and about 1,000,000,000 gates… (MIT 2017 - Quantum Computational Supremacy)

Today's Noisy Intermediate Scale Quantum (NISQ) processor have about 100 "imperfect" (noisy) qubits… Coherence time of qubits is around milli- to micro-second

With today's technology and knowledge, one would need approximately:

4,000,000 qubits that would not negatively interfere too much with each other and stay coherent for a significant amount of time…

## Breaking current encryption schemes

A 2,048 bit integer might *never* be factored on a quantum processor…

Not very likely in the next half century…

Generated with dreamstudio.ai

# Impact of Shor's algorithm

## Post-quantum cryptography

Development of post-quantum cryptography (quantum-proof / quantum-resistant schemes)

NIST Post-Quantum Cryptography Standardization

Competition started in 2016: lattice, code-based, hash-based algorithms…

2022-07-05: First winners for standardization: lattice based (CRYSTALS-Kyber) and hash-based (SPHINCS+)

3. What are the problems ?

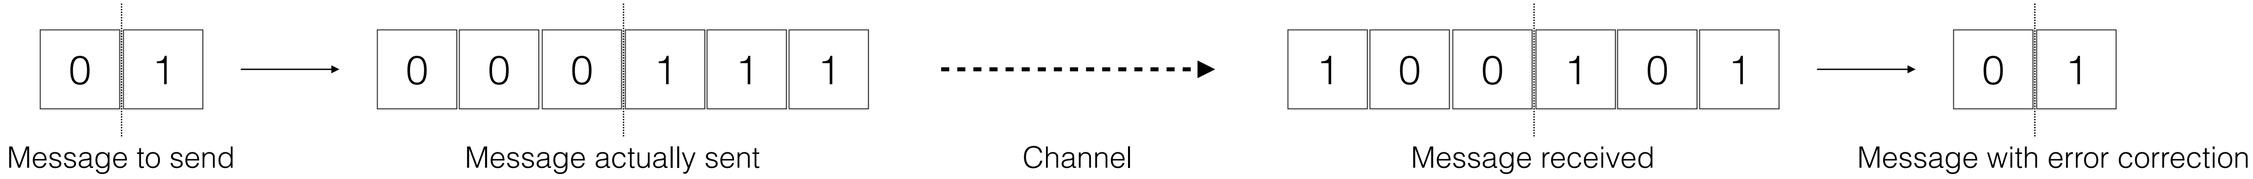
# Problems

1. Noise (need for error correction
2. Quantum decoherence
3. Scaling up

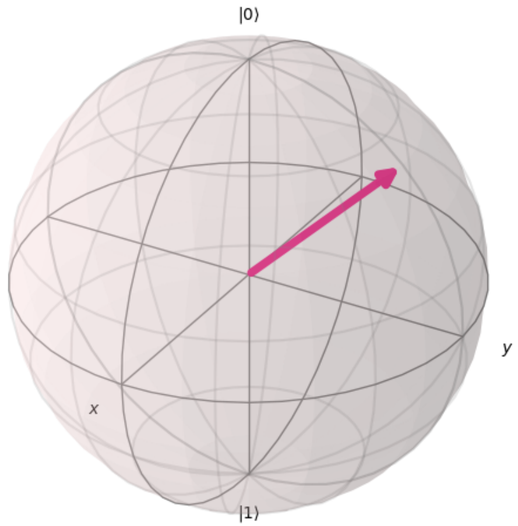
# 1. Noise / Error correction

## Classical computing (classical bit)

Basic error correction scheme: *3* physical bits sent for *1* logical bit of information



## Quantum computing (quantum bit)

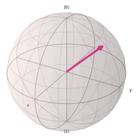


Vector of 2 complex values

Currently approx. *1,000* physical qubits for *1* logical qubit

Need for: Work on error correction schemes

# 2. Decoherence



## Issue

After a very short time (milli to micro-seconds in a superconducting processor), qubits *lose* their coherence (*state*).

## Impact

Circuits can only have a *limited number of gates* for a computation to remain meaningful

Find algorithms that require less gates.

Limit use of complex gates that need to be expressed (compiled into) multiple basis gates.

## Need for

Limiting external noise (cryogenics / low temperature physics)

Limiting noise among qubits

…

# 3. Scaling up

## Issue / fact

Today's quantum processors have in the order of *100* qubits

Factoring a 2,048 bit integer (Shor's algorithm / RSA cryptosystem) requires 4,000 logical (perfect) qubits,
Or approximately *4,000,000* of today's noisy (imperfect) physical qubits.

Each qubit adds noise for the other qubits

Each qubit is controlled by a co-axial cable (electromagnetic field)

## Need for

Work on quantum error correction (needing less physical qubits to implement a logical qubit)

Architecture (how to arrange the qubits), limit noise from neighbouring qubits

…

# 4. Potential future applications

edX coursera — Numerous university courses from Stanford, UofT, UBC, Purdue, EPFL, X, …

Looking Glass Universe (Youtube channel)

Quantum Computing Expert Explains One Concept in 5 Levels of Difficulty

# Summary

A quantum processor will *never* replace a classical computer

“any computational problem that can be solved by a quantum computer can also be solved by a classical computer” (IBM)

“*might* provide *faster* solutions to *some* computational problems” (IBM); e.g. modelling molecules (quantum chemistry)

Still very early stage… quantum mechanics (100 years old), idea to build a quantum processor (40 years old)

Governments are preparing: education, research, commercialization

Preparing for quantum resistant encryption algorithms (just in case, better be prepared than sorry)

Large companies, banks, governments are experimenting / learning on potential use cases with current error prone quantum processors

Notation, varia, …

# Advantages of quantum processors

## IBM fundamentals of quantum computing

"might provide *faster* solutions to some computational problems"

"may allow us to solve certain computational problems that classical computers are too slow to solve"

"any computational problem that can be solved by a quantum computer can also be solved by a classical computer"

# Basics of quantum information - Classical information

**States** of a classical bit

$X$: system begin considered e.g. a bit

$\Sigma = \{0,1\}$ possible states assumed by the bit

**Probabilistic state**: Assume we believe X is in state 0 with probability 3/4 (resp. in state 1 with prob. 1/4)

$$\begin{pmatrix} \frac{3}{4} \\ \frac{1}{4} \end{pmatrix} \begin{matrix} 0 \\ 1 \end{matrix}$$

**Measuring probabilistic states**

“we can never "see" a system in a probabilistic state” (source: IBM Quantum learning)

“a measurement will yield exactly one of the allowed classical states” (source: IBM Quantum learning)

We see either state 0 and state 1 (standard basis vector)

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \qquad |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \qquad \begin{pmatrix} \frac{3}{4} \\ \frac{1}{4} \end{pmatrix} = \frac{3}{4}|0\rangle + \frac{1}{4}|1\rangle$$

# Flip of a fair coin

**Example**: a flip of a fair coin has equal probability to fall on heads and tails

**Original** probabilistic state: $\begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix} = \frac{1}{2}|heads\rangle + \frac{1}{2}|tails\rangle$

State set of a coin: $\Sigma = \{heads, tails\}$

**Observed** state: either $|heads\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ or $|tails\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$

Quantum systems behave in an analogous way: observed states are one of the basic states (not a combination)

# Deterministic operations (matrix vector multiplication)

Deterministic operations on probabilistic states can be represented as a *matrix vector multiplication*.

E.g. NOT operation: $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ If applied on state $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ Results in $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$

**Bra notation**: $\langle a|$ for **row vectors**

$\langle a|$ is the row vector having a 1 in entry corresponding to $a$ and 0 elsewhere

For $\Sigma = \{0,1\}$, we have $\langle 0| = (1\ 0)$ and $\langle 1| = (0\ 1)$

**Ket notation**: $|a\rangle$ for **column vectors**

$|a\rangle$ is the column vector having a 1 in entry corresponding to $a$ and 0 elsewhere

For $\Sigma = \{0,1\}$, we have $|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $|1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$

## Quantum state vectors

Indices label the classical states of the system; e.g. for 3-bit system:

$$\begin{pmatrix} \alpha_0 \\ \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \\ \alpha_5 \\ \alpha_6 \\ \alpha_7 \end{pmatrix} \begin{matrix} 000 \\ 001 \\ 010 \\ 011 \\ 100 \\ 101 \\ 110 \\ 111 \end{matrix}$$

1. **The entries $\alpha_i$ are complex numbers**
2. The sum of absolute values squared of entries $\alpha_i$ equals 1: $\Sigma_i |\alpha_i|^2 = 1$

Quantum state vectors are unit vectors (Euclidean norm of 1.0)

## Example of a qubit state

$$|\psi\rangle = \begin{pmatrix} \frac{1+2i}{3} \\ \frac{-2}{3} \end{pmatrix} = \frac{1+2i}{3}|0\rangle - \frac{2}{3}|1\rangle$$

## **Measuring quantum states** (*standard basis* measurement)

"measurements act as the interface between quantum and classical information" (source: IBM learning)

each classical state results with probability equal to absolute value squared of the entry

E.g. a 3 bit quantum state: the classical state $010$ appears with probability $|\alpha_2|^2$

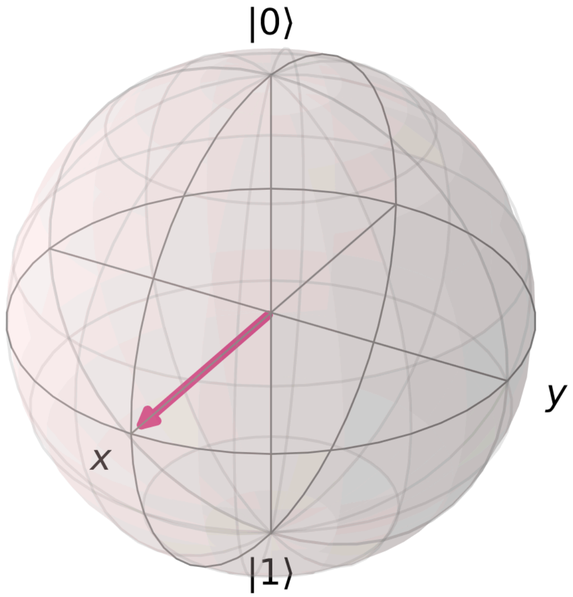
$$\psi = \begin{pmatrix} \alpha_0 & 000 \\ \alpha_1 & 001 \\ \alpha_2 & 010 \\ \alpha_3 & 011 \\ \alpha_4 & 100 \\ \alpha_5 & 101 \\ \alpha_6 & 110 \\ \alpha_7 & 111 \end{pmatrix}$$

# Unitary matrix operations (reversible) on a single qubit

**Pauli operations**

$$I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \sigma_x/X = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \sigma_y/Y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \sigma_z/Z = \begin{pmatrix} 1 & 0 \\ 0 & -i \end{pmatrix}$$

identity NOT (bit flip) phase flip



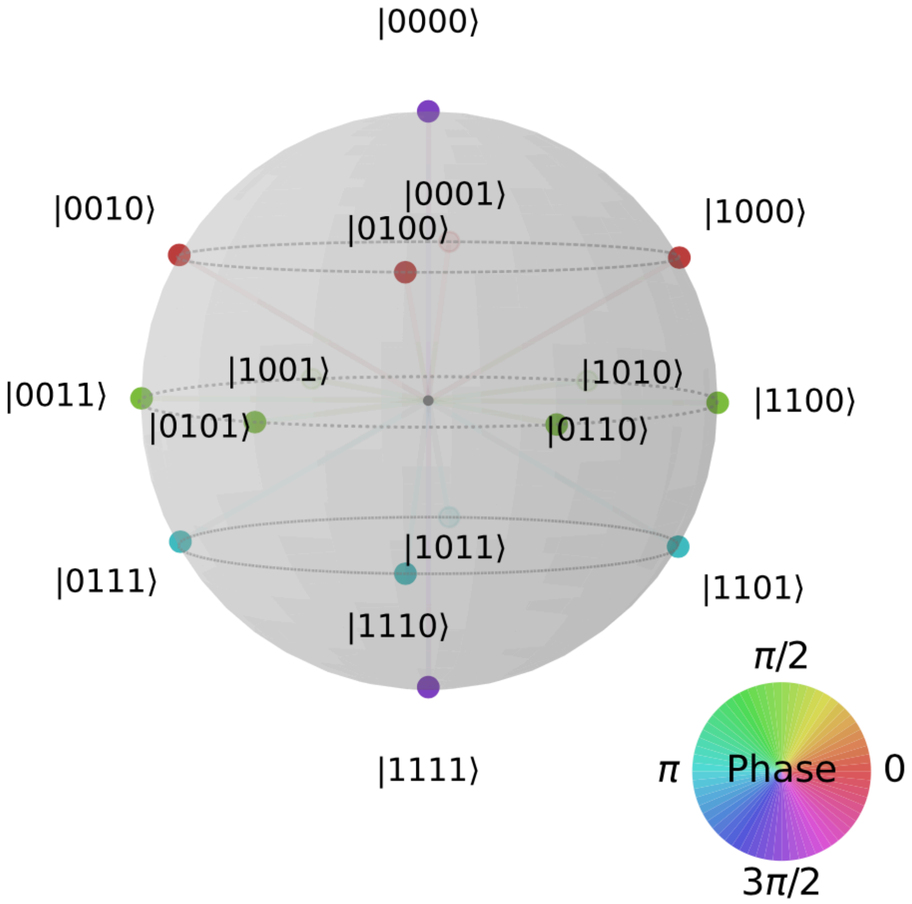
**Hadamard operation**

$$H = \begin{pmatrix} \frac{1}{\sqrt{(2)}} & \frac{1}{\sqrt{(2)}} \\ \frac{1}{\sqrt{(2)}} & -\frac{1}{\sqrt{(2)}} \end{pmatrix}$$

**Phase operations**

$$P_\theta = \begin{pmatrix} 1 & 0 \\ 0 & e^{i\theta} \end{pmatrix} \quad \text{e.g.} \quad S = P_{\pi/2} = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix} \quad T = P_{\pi/4} = \begin{pmatrix} 1 & 0 \\ 0 & \frac{1+i}{\sqrt{(2)}} \end{pmatrix}$$

# Representation of multi qubit states using Bloch sphere



# Bell's inequality

A tautology, obviously true, proved with logic and integers

$$N(A, \bar{B}) + N(B, \bar{C}) \geq N(A, \bar{C})$$

$$N(A, \bar{B}, C) + N(A, \bar{B}, \bar{C}) \; + \; N(A, B, \bar{C}) + N(\bar{A}, B, \bar{C}) \quad \geq \quad N(A, B, \bar{C}) + N(A, \bar{B}, \bar{C})$$
